Outline

linked lists

mutation

linked list queues
why linked lists?

regular Python lists are flexible and useful, but overkill in some situations — they allocate large blocks of contiguous memory, which becomes increasingly difficult as memory is in use. linked list nodes reserve just enough memory for the object value they want to refer to, a reference to it, and a reference to the next node in the list.
linked lists, two concepts

There are two useful, but different, ways of thinking of linked list nodes

1. as lists made up of an item (value) and a sub-list (rest)

2. as objects (nodes) with a value and a reference to other similar objects

For now, will take the second point-of-view, and design a separate “wrapper” to represent a linked list as a whole.
class LinkedListNode:
    
    Node to be used in linked list

    === Attributes ===
    next_ - successor to this LinkedListNode
    value: data this LinkedListNode represents
    
    next_: LinkedListNode
    value: object

    def __init__(self, value: object, next_: LinkedListNode=None) -> None:
        
        Create LinkedListNode self with data value and successor next_.

        self.value, self.next_ = value, next_
a wrapper class for list

The list class keeps track of information about the entire list — such as its front, back, and size.

class LinkedList:
    
    """
    Collection of LinkedListNodes
    """

    === Attributes ==
    front - first node of this LinkedList
    back - last node of this LinkedList
    size - number of nodes in this LinkedList, >= 0
    """

    front: LinkedListNode
    back: LinkedListNode
    size: int

    def __init__(self):
        """
        Create an empty linked list.
        """
        """
        self.front, self.back, self.size = None, None, 0
division of labour

Some of the work of special methods is done by the nodes:

- `__str__`

- `__eq__`

Once these are done for nodes, it’s easy to do them for the entire list.
walking a list

Make a reference to (at least one) node, and move it along the list:

cur_node = self.front
while <some condition here...>:
    # do something here...
    cur_node = cur_node.nxt
prepend
create a new node and add it before self.front...
Check (possibly) every node

cur_node = self.front
while <some condition here…>:
    # do something here...
    cur_node = cur_node.nxt
__getitem__

Should enable things like

```python
>>> print(lnk[0])
5

... or even

>>> print(lnk[0:3])
5 -> 4 -> 3 ->|
```
We’ll need to change...

- last node
- former last node
- back
- size
- possibly front

draw pictures!!
We need to find the second last node. Walk two references along the list.

```python
prev_node, cur_node = None, lnk.front
# walk along until cur_node is lnk.back
while <some condition>:
    prev_node = cur_node
    cur_node = cur_node.nxt
```
something linked lists do better than lists?

list-based Queue has a problem: adding or removing will be slow.
symmetry with linked list

which end of a linked list would be best to add, which to remove? why??
build pop_front

... already have append
revisit Queue API

use an underlying LinkedList
revisit Stack API while we’re at it

also use an underlying LinkedList
they’re all Containers

stress drive them through `container_cycle`, in `container_timer.py`:

- list-based Queue
- linked-list-based Queue
- list-based Stack
- linked-list-based Stack
what matters is the growth rate

as Queue grows in size, list-based-Queue bogs down, becomes impossibly slow
notes...
