Design Patterns
CSC207 Fall 2017
Design Patterns

A **design pattern** is a general description of the solution to a well-established problem using an arrangement of classes and objects.

Patterns describe the shape of code rather than the details.

They’re a means of communicating design ideas.

They are not specific to any one programming language.

You’ll learn about lots of patterns in CSC301 (Introduction to Software Engineering) and CSC302 (Engineering Large Software Systems).
Reminder: loose coupling, high cohesion

These are two goals of object-oriented design.

**Coupling**: the interdependencies between objects. The fewer couplings the better, because that way we can test and modify each piece independently.

**Cohesion**: how strongly related the parts are inside a class. High cohesion means that a class does one job, and does it well. If a class has low cohesion, then an object has parts that don’t relate to each other.

Design patterns are often applied to decrease coupling and increase cohesion.
Gang of Four

First codified by the Gang of Four in 1995
  - Erich Gamma, Richard Helm, Ralph Johnson, and John Vlissides

Original Gang of Four book described 23 patterns
  - More have been added
  - Other authors have written books
Book provides an overview of:

- **Name**
- **Problem**: when to use the pattern
  - motivation: sample application scenario
  - applicability: guidelines for when your code needs this pattern
- **Solution**:
  - structure: UML Class Diagram of generic solution
  - participants: description of the basic classes involved in generic solution
  - collaborations: describes the relationships and collaborations among the generic solution participants
  - sample code
- Consequences, Known Uses, Related Patterns, Anti-patterns
Iterator Design Pattern

Context

- A container/collection object.

Problem

- Want a way to iterate over the elements of the container.
- Want to have multiple, independent iterators over the elements of the container.
- Do not want to expose the underlying representation: should not reveal how the elements are stored.
Iterator Design Pattern: Java
Observer Design Pattern

Problem:

- Need to maintain consistency between related objects.
- Two aspects, one dependent on the other.
- An object should be able to notify other objects without making assumptions about who these objects are.
Observer: Java Implementation

```java
Observable
- observers
+ addObserver(o: Observer): void
+ deleteObserver(o: Observer): void
+ deleteObservers(): void
+ hasChanged(): boolean
+ setChanged(): void
+ clearChanged(): void
+ notifyObservers(): void
+ notifyObservers(arg: Object): void

if hasChanged():
  for all o: observers:
    o.update(this, agr)
  clearChanged()

YourObservableClass
- state
  + getState()
  + setState()

Observer
+ update(o: Observable, arg: Object)

YourObserverClass
- observerState
```
Observer: Example in Java

```java
class Observable {
    List<Observer> observers;

    public addObserver(Observer o) {
        observers.add(o);
    }

    public deleteObserver(Observer o) {
        observers.remove(o);
    }

    public deleteObservers() {
        observers.clear();
    }

    public boolean hasChanged() {
        return dirty;
    }

    public void setChanged() {
        dirty = true;
    }

    public void clearChanged() {
        dirty = false;
    }

    public void notifyObservers() {
        for (Observer o : observers) o.update(this, arg);
    }

    public void notifyObservers(Observer o, int arg) {
        o.update(this, arg);
    }
}

interface Observer {
    void update(Observable o, Object arg);
}

class Company {
    String name;

    public String toString() {
        return "Company: \" + name + \"\";
    }
}

class Customer {
    String name;

    public String toString() {
        return "Customer: \" + name + \"\";
    }
}

class Parcel {
    String trackingNumber, location;

    public String getTrackingNumber() {
        return trackingNumber;
    }

    public String getLocation() {
        return location;
    }

    public void setTrackingNumber(String trackingNumber) {
        this.trackingNumber = trackingNumber;
    }

    public void setLocation(String location) {
        this.location = location;
    }

    public void updateLocation(String loc) {
        location = loc;
    }

    public String toString() {
        return "Parcel: Tracking Number: \" + trackingNumber + \", Location: \" + location + \"\";
    }
}
```
Strategy Design Pattern

Problem:

- multiple classes that differ only in their behaviour (for example, use different versions of an algorithm)
- but the various algorithms should not be implemented within the class
- want the implementation of the class to be independent of a particular implementation of an algorithm
- the algorithms could be used by other classes, in a different context
- want to **decouple** — separate — the implementation of the class from the implementations of the algorithms
Strategy: Standard Solution
Example: without the Strategy pattern
Example: using the Strategy pattern

```
Author
- name: String
- books: List<Book>
- sorter: Sorter<Book>
+ Author(name: String, sorter: Sorter)  
+ getName(): String
+ setName(): void
+ addBook(book: Book): void
+ sortBooks(): void
+ toString(): String

Comparable<T>
compareTo(other: T): int

Book
- name: String
- isbn: String
+ Book(name: String, isbn: String)
+ getName(): String
+ setName(): void
+ getISBN(isbn: String): void
+ setISBN(): void
+ compareTo(other: Book): int
+ toString(): String

SelectionSorter<T>
+ sort(list: List<T>): void

InsertionSorter<T>
+ sort(list: List<T>): void
```
Model-View-Controller (MVC) Design Pattern

- **Model**: data, rules that govern access to the data, interactions that update the data
  - Often approximates a real-world process

- **View**: presentation of that data that is responsive to changes in the model
  - With a Push Model, the View receives change notifications from the Model
  - With a Pull Model, the View is responsible for calling the model and retrieving the most current data.
• Controller: Interaction between User and View are translated by the Controller into actions for the Model to perform.

The controller can call different aspects of the View (close one window and/or open another)

• Graphical User Interfaces (GUI) often comprise the View, where the Controller is the non-visual front end (e.g., what the buttons interact with when they are clicked), and the Model is the data which the GUI displays and with which the User interacts via the Controller.
MVC Pattern: General Structure

- From:
  - https://www.tonymarston.net/php-mysql/model-view-controller-01.png
MVC: What’s happening inside?
• Code for this example can be found here:

• https://www.tutorialspoint.com/design_pattern/mvc_pattern.htm
Dependency in Object Oriented Programming

• A “dependency” relationship between two classes (also called “using” relationship) means that any change to the second class will change the functionality of the first.

• For example: class AddressBook depends on class Contact because AddressBook contains instances of Contact.

• Other examples of dependencies: loggers, handlers, listeners
Dependency Injection Design Pattern

Problem:

- We are writing a class, and we need to assign values to the instance variables, but we don’t want to hard-code the types of the values. Instead, we want to allow subclasses as well.
Dependencies in Java

• Using operator `new` inside the first class can create an instance of a second class that cannot be used nor tested independently. This is called a “hard dependency”.

• We often want to use and test the second class independently from the first and avoid hard dependencies. For example:

```java
public class MyClass {
    private Student student;

    public MyClass(Student student) {
        this.student = student;
    }
}
```
Dependency Injection Example

- Interface MovieFinder
  - findAll(): List<Movie>

- Class Movie
  - director: String
  - getDirector(): String
  - movie(): List<Movie> «create»

- Class SemiColonDelimitedMovieFinder
  - filename: String
  - setFilename(filename: String): void
  - findMovie(): List<Movie> «create»
  - setMovie(SemiColonDelimitedMovieFinder finder): void
Dependency Injection Pattern
Exercise

• Consider our previous example of class Person and its subclass Student.

• Create a class called Email that contains instance variables of type String called: to, from, cc, subject, and message. It should also contain methods printToScreen and printToFile methods.

• Class Person should have the ability to send an Email object to another Person object. But that will require our first instance of Person to obtain the second Person object’s name or email address.
Without Dependency Injection:

The code for creating and sending an email will have to be inside class Person.

Any change to the Email class will impact the code in class Person.
With Dependency Injection:

We can create a class called `EmailService` that gathers the information required to compose and send `Email` objects.

The constructor for `EmailService` can take in the entire `Person` sender object and `Person` receiver object and retrieve the values of their respective `name` and `email` fields, in order to create a new instance of `Email`.

Any change to the `Email` class will be contained by the `EmailService` and shielded from class `Person`. 
Factory Design Pattern

Problem:

- A class cannot anticipate the class of the object it must create.
- A class wants its subclasses to specify the object it creates.
- Classes delegate responsibility to one of several helper subclasses and you want to localize knowledge of which helper subclass is the delegate.
When to use Factory Method Design Pattern

- One class wants to interact with many possible related objects.
- We want to obscure the creation process for these related objects.
- At a later date, we might want to change the types of the objects we are creating.
Factory Method: A Standard Solution
Factory Pattern: An example
• Code for this example can be found here:

• https://www.tutorialspoint.com/design_pattern/factory_pattern.htm
• We can easily create new subclasses of Shape and use the ShapeFactory to instantiate them without changing the rest of the code.
Factory Pattern: Another Example

```
Document
  Open()
  Close()
  Save()
  Revert()

MyDocument

Application
  CreateDocument()
  NewDocument()
  OpenDocument()

Document* doc = CreateDocument();
docs.Add(doc);
doc->Open();

MyApplication
  CreateDocument()

return new MyDocument
```
• For implementation of the Document Example, see:
