### Outline

performance

binary search tree

big-oh

### performance...

We want to measure algorithm performance, independent of hardware) programming language, random events

g elements on a lat, e.g.

Focus on the size of the input) call it n. How does this affect the resources (e.g. processor time) required for the output? If the relationship is linear, our algorithm's complexity is O(n)roughy proportional to the input size n.

list searching  $n \leq 2^{k}$ Liq  $n \leq k$ You've already seen algorithms for skeing whether an element is contained in a list: [97, 36, 48, 73, 156, 947, 56, 236] What is the performance of these algorithms in terms of list size? What about the analogous algorithm for a tree? Jineon search. ()(n) | if list is already sorted; try bina 14 search.

Computer Science

(日) (四) (日)

### a more efficient binary tree

We need to impose a sorting condition on binary trees. A binary search tree is:  $P(s^{V}, led)$ 

- ▶ a binary tree
- left subtree of every node contains only values smaller than those of that node
- right subtree of every node contains only values greater than those of that node

(日)

# efficiency?

Binary search of a list allowed us to ignore (roughly) half the list. Searching a binary search tree allows us to ignore the left or right subtree. AVL trees, red-black trees.

If we're searching the tree rooted at node n for value v, then one of three situations are possible:

- node n has value v
- $\triangleright$  v is less than node n's value, so we should search to the left
- ► v is more than node n's value, so we should search to the right fire Subtrees.

イロト イヨト イヨト イ

insert

Inserting is closely related to finding a node:

▶ if we find a node in our tree, no need to insert it!

▶ otherwise, we find the spot it should be, and insert it there.

deleting is a bit trickier, because there are several scenarios to consider, even after we've figured out which node we wish to delete:

▶ if the node we wish to delete is a leaf, just delete it

deleting

- ▶ if the node we wish to delete has exactly one child, replace it with the other
- ▶ if the node we wish to delete has two children, replace it with the largest child in its left subtree...

You should draw some diagrams until you understand these scenarios
