Course notes, chapter 5

## Outline

infinities and functions

## some assignment 3 questions

notes
$\equiv \Rightarrow \quad$ 三 $\quad$ 〇の
recall $f: \mathbb{N} \mapsto\{$ even natural numbers $\}$
$f(n)=2 n$ is onto and $1-1$

4 三 $\quad$ 三

## rational numbers， $\mathbb{Q}$ are countable

Show a list，i．e．some $f: \mathbb{N} \mapsto \mathbb{Q}$ that is onto

ミD 引 ミQく

## Cantor's example

To show that the set of infinite decimals in $[0,1]$ was bigger than the natural numbers, Cantor showed that any so-called list of these numbers would always miss entries:

| list position | decimal |
| :--- | :--- |
| 0 | $0.000000000000 \cdots$ |
| 1 | $0.010101010101 \cdots$ |
| 2 | $0.012012012012 \cdots$ |
| 3 | $0.012301230123 \cdots$ |
| $\vdots$ | $\vdots$ |

No matter how you try to generate the list it will omit the number formed by taking ' 0 .' and then traversing the diagonal and changing the digit by adding 1 (if it's not a 9 ), and subtracting 1 (if it's a 9 ).
This means that the real numbers (which contain $[0,1]$ ) larger infinity than the natural numbers.

## two specifications of a function

A precise, but infeasible, specification of a function is its behaviour on every input:

```
def f(n) :
    if n == 0 : return 3
    if n == 1 : return 4
    if n == 2 : return 5
    # ...
    if n == "foo" : # throw a type error
```

Or you could write a procedure to computer its behaviour:
def $f(n)$ :
return n + 3
There are more ways to do the former than the latter. So many more that they don't match up...!

## how many python functions?

Every python function can be written in UTF-8, as a string of characters and whitespace out of 256 characters to define a function:
def $\mathrm{f}(\mathrm{n})$ :

```
return n + 3
```

Each string can be converted to a different number by treating each character as a digit in base 256. This gives us an onto function from $\mathbb{N}$ to the set of python programs - there are countably many python functions.

## diagonalization

Make a column of each of the countably many python functions. In each row, list the behaviour of whether that function halts or loops given another function as input:

|  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Function f | $\mathrm{H}(\mathrm{f}, \mathrm{f0})$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 1)$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 2)$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 3)$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 4)$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 5)$ | $\mathrm{H}(\mathrm{f}, \mathrm{f} 6)$ |
| f0 | halts | halts | halts | halts | halts | halts | halts |
| f1 | loops | loops | loops | loops | loops | loops | loops |
| f2 | halts | loops | halts | loops | halts | loops | halts |
| f3 | halts | loops | loops | halts | loops | loops | halts |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
|  |  |  |  |  |  |  |  |

If you toggle the diagonal - switch loops to halts and vice-versa - you will get the behaviour of a "function" that can't possibly be on the list navel_gaze. There are more (a larger infinity) of behaviours than python functions.
$\lim _{n \rightarrow \infty}\left(5 n^{3}+3 n+7\right) /\left(2 n^{3}+4 n+8\right)=5 / 2$
What does that tell us about big-Oh, big-Omega?

## another uncomputable function

```
def halt(f,i):
    def initialized(g,v):
    """ g initializes v on every possible input """
    ...code for initialized goes here...
    # Put some code here to scan the code for f and figure out
    # a variable name that doesn't appear, and store it in v
    def f_prime(x):
    # Ignore the argument x, call f with the fixed argument
    # (the one passed in to halt).
    f(i)
    exec("print " + v) #
return not initialized(f_prime,v)
```
