Learning Objectives

By the end of this worksheet, you will:

- Translate sentences between natural English and predicate logic.
- Determine the truth value of sentences on small domains.
- Define a property of a mathematical function using predicate logic.
- Express conditions on domains in predicate formulas.

1. Alternating quantifiers. Consider the following table that shows the employees of a (very small) company:

<table>
<thead>
<tr>
<th>Employee</th>
<th>Salary</th>
<th>Department</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aizah</td>
<td>60,000</td>
<td>Sales</td>
</tr>
<tr>
<td>Betty</td>
<td>15,000</td>
<td>Sales</td>
</tr>
<tr>
<td>Carlos</td>
<td>40,000</td>
<td>HR</td>
</tr>
<tr>
<td>Doug</td>
<td>30,000</td>
<td>Sales</td>
</tr>
<tr>
<td>Ellen</td>
<td>50,000</td>
<td>Design</td>
</tr>
<tr>
<td>Flo</td>
<td>20,000</td>
<td>Design</td>
</tr>
</tbody>
</table>

Let $E$ be the set of the six employees listed above. We’ll define two predicates on this set:

- $\text{Rich}(x)$: “$x$ earns more than 35,000,” where $x \in E$
- $\text{SameDept}(x, y)$: “$x$ and $y$ are in the same department,” where $x, y \in E$

(a) Consider the statement

$$\exists x, y \in E, \text{Rich}(x) \land \text{SameDept}(x, y).$$

Give one example to show that this statement is True. Is there more than one possible answer? Note: just as in programming and math, the two variables $x$ and $y$ can have the same value (i.e., refer to the same employee).

**Solution**

$x = \text{Aizah}$ and $y = \text{Aizah}$ is one possibility. A good exercise is to try to find all possibilities.

(b) Here’s the same statement, but with a universal quantifier instead:

$$\forall x, y \in E, \text{Rich}(x) \land \text{SameDept}(x, y).$$

Give one counter-example to show that this statement is False. Is there more than one possible answer?

**Solution**

Lots of possibilities here! We can pick an employee who isn’t rich, e.g. $x = \text{Betty}$ and $y = \text{Aizah}$. Or, we could pick two employees who aren’t in the same department, e.g. $x = \text{Aizah}$ and $y = \text{Carlos}$.

(c) Now let’s look at alternating quantifiers.

$$\forall y \in E, \exists x \in E, \text{Rich}(x) \land \text{SameDept}(x, y).$$

Is this True or False? How do you know?

---

1This example is adapted from an old set of CSC165 course notes.
Solution

This is True. The translation is “for every employee \( y \), there is an employee \( x \) who has a salary greater than 30,000 and in the same department as \( y \).” Each department has an employee with a salary greater than 30,000, so for each employee \( y \), we can always pick an employee \( x \) in the same department who is “rich”.

For example, when \( y = \text{Betty} \), we can pick \( x = \text{Aizah} \) (can you list all possibilities?). Note that the HR department only has one employee! So if \( y = \text{Carlos} \), we would also pick \( x = \text{Carlos} \) to make this statement True.

(d) With the quantifiers switched:

\[ \exists x \in E, \forall y \in E, \text{Rich}(x) \land \text{SameDept}(x, y). \]

Explain why this statement is False.

Solution

This statement says that there is an employee \( x \) who has a salary greater than 30,000 and where every employee is in the same department as \( x \). This is False, since there are employees in different departments.

For example, if \( x = \text{Aizah} \), while \( \text{Rich}(x) \) is True, it’s not true that \( \text{SameDept}(x, y) \) for all employees \( y \).

2. A property of functions. Let \( f : \mathbb{R} \rightarrow \mathbb{R} \) be a function. Recall that the co-domain of \( f \) is the set after the \( \rightarrow \) symbol (in this case, \( \mathbb{R} \)), which contains the possible output values of \( f \). However, in general the co-domain of a function might contain values that cannot possibly be output (e.g., if \( f : \mathbb{R} \rightarrow \mathbb{R} \) is defined as \( f(x) = x^2 \)). We say that \( f : \mathbb{R} \rightarrow \mathbb{R} \) is onto if and only if its co-domain \( \mathbb{R} \) only contains values that could possibly be output by \( f \) (and no “impossible” values). For example, \( f(x) = x^2 \) is not onto, but \( f(x) = x + 1 \) is onto.

(a) Let \( f : \mathbb{R} \rightarrow \mathbb{R} \). Express the statement “\( f \) outputs 10 (for at least one input)” in symbolic form. You may use an expression like \( f(x) = 10 \) in your statement.

Solution

\[ \exists x \in \mathbb{R}, \ f(x) = 10. \]

(b) Now express the definition of onto as a predicate in symbolic form by filling in the following blank.

\[ \text{Onto}(f) : \quad , \text{where} \ f : \mathbb{R} \rightarrow \mathbb{R}. \]

Solution

\[ \forall y \in \mathbb{R}, \exists x \in \mathbb{R}, \ f(x) = y. \]

(c) Let \( f(x) = x^2 \). Give a counter-example to show that \( f \) is not onto.

Solution

Because \( x^2 \) is always greater than or equal to 0, if we pick \( y = -1 \), the statement \( \exists x \in \mathbb{R}, \ x^2 = -1 \) is False!
3. **Expressing conditions.** Often when we want to express statements using predicate logic, the common domains like \( \mathbb{N} \) and \( \mathbb{R} \) do not quite fit. For example, consider the statement:

Every natural number greater than 3 is greater than 1.

The use of "every" suggests a universal quantification, but using the domain of \( \mathbb{N} \) in the following way does not capture the full meaning of the statement:

\[ \forall n \in \mathbb{N}, \; n > 1 \]

In this question, you’ll explore two equivalent ways of modifying the above formula to capture the condition “greater than 3.”

(a) One simple way is to change the domain over which we’re quantifying. Write down the definition of a set \( S \) such that the following formula is equivalent to the original statement:

\[ \forall n \in S, \; n > 1 \]

**Solution**

\[ S = \{ n \mid n \in \mathbb{N} \text{ and } n > 3 \} \]

(b) We’ve hinted at another way to express this statement by using the word “condition” to describe the role of “greater than 3.” The original statement only talks about natural numbers greater than 3, and ignores all others—the same is true of the implication operator. This suggests that we can keep the original domain, but use an implication to narrow the scope of what we’re talking about.

Define a predicate \( P(n) \) such that the following formula is equivalent to the original statement:

\[ \forall n \in \mathbb{N}, \; P(n) \Rightarrow n > 1 \]

**Solution**

\[ P(n) : n > 3, \text{ where } n \in \mathbb{N} \]

(c) Using what you’ve learned, express the following statement in *two different* ways:

Every integer that is greater than 10 or less than -40 is not equal to 0.

**Solution**

Using the domain \( S = \{ x \mid x \in \mathbb{Z} \text{ and } x > 10 \text{ or } x < -40 \} \),

\[ \forall x \in S, \; x \neq 0 \]

Using the predicate \( P(x) : "x > 10 \lor x < -40" \),

\[ \forall x \in \mathbb{Z}, \; P(x) \Rightarrow x \neq 0 \]

or simply

\[ \forall x \in \mathbb{Z}, \; x > 10 \lor x < -40 \Rightarrow x \neq 0 \]
