Studen	t Nuı	mber	:										

- This examination has 4 questions. There are a total of 10 pages, DOUBLE-SIDED.
- All statements in predicate logic must have negations applied directly to propositional variables or predicates.
- In your proofs, you may always use definitions we have covered in this course. However, you may **not** use any external facts about these definitions unless they are given in the question.
- For algorithm analysis questions, you can jump immediately from an exact step count to an asymptotic bound without proof (e.g., write "the number of steps is  $3n + \lceil \log n \rceil$ , which is  $\Theta(n)$ ").

Take a deep breath.

This is your chance to show us how much you've learned.

We **WANT** to give you the credit that you've earned.

A number does not define you.

Good luck!

Question	Grade	Out of
Q1		7
Q2		5
Q3		6
Q4		9
Total		27

- 1. [7 marks] Short answer. You do not need to show your work for any part of this question.
  - (a) [1 mark] Write down the binary representation of the decimal number 100. The representation should not have any leading zeros. HINT:  $2^3 = 8$ ,  $2^4 = 16$ ,  $2^5 = 32$ ,  $2^6 = 64$ .

```
Solution
100 = (1100100)_2
```

(b) [1 mark] Let  $n \in \mathbb{Z}^+$ . What is the *smallest* number that can be expressed by an *n*-digit balanced ternary representation? (Your answer should be in terms of n and can be in the form of a summation.)

```
Solution
\sum_{i=0}^{n-1} (-1) \cdot 3^i = -\sum_{i=0}^{n-1} 3^i = \frac{1-3^n}{2}
```

(c) [2 marks] Let  $f(n) = n^2 + 10n + 2$  and  $g(n) = 100 \log_2 n$ . For each statement below, check one box to indicate whether the statement is true or false.

```
TRUE FALSE TRUE FALSE TRUE FALSE TRUE FALSE f(n) \in \Omega(n) \quad \boxed{\hspace{-0.2cm} \int} \qquad g(n) \in \Omega(n) \quad \boxed{\hspace{-0.2cm} \int} \qquad f(n) \in \mathcal{O}(g(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad f(n) + g(n) \in \Theta(f(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int} \qquad f(n) + g(n) \in \Theta(f(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int} \qquad f(n) + g(n) \in \Theta(f(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int} \qquad f(n) + g(n) \in \Theta(f(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int} \qquad f(n) + g(n) \in \Theta(f(n)) \quad \boxed{\hspace{-0.2cm} \int} \qquad \boxed{\hspace{-0.2cm} \int
```

(d) [1 mark] Consider the following algorithm.

```
def f(n: int) -> None:
    """Precondition: n >= 0."""
    i = 3
    while i * i < n:
        i = i * i</pre>
```

Find a formula for  $i_k$ , the value of variable i after k iterations (where  $k \in \mathbb{N}$ ).

```
Solution i_k = 3^{2^k}
```

(e) [2 marks] Use your answer from the previous part to find the exact number of iterations this function's loop will run. Use floor or ceiling to ensure that the number of iterations is an integer.

# Solution

We need to find the smallest value of k that satisfies the inequality  $i_k^2 \ge n$ , i.e.,  $\left(3^{2^k}\right)^2 \ge n$ .  $k = \lceil \log_2(\log_3 n) - 1 \rceil$ 

2. [5 marks] Induction. Prove the following statement using induction.

$$\forall n \in \mathbb{N}, \ n \ge 3 \Rightarrow 5^n + 50 < 6^n$$

HINT:  $5^3 = 125$  and  $6^3 = 216$ .

### **Solution**

*Proof.* We'll prove this statement by induction on n.

Base case: let n = 3. We'll prove that  $5^n + 50 < 6^n$ .

The left side is  $5^n + 50 = 5^3 + 50 = 175$ . The right side is  $6^n = 6^3 = 216$ , and so  $5^n + 50 < 6^n$ .

<u>Induction step</u>: let  $k \in \mathbb{N}$ , and assume that  $k \geq 3$  and that  $5^k + 50 < 6^k$ . We'll prove that  $5^{k+1} + 50 < 6^{k+1}$ . We start with the left side of our desired inequality:

$$5^{k+1} + 50 = 5 \cdot 5^k + 50$$

$$= 4 \cdot 5^k + 5^k + 50$$

$$< 4 \cdot 5^k + 6^k$$
 (by the I.H.)
$$< 5 \cdot 6^k + 6^k$$
 (since  $4 < 5$  and  $5^k < 6^k$ )
$$= 6 \cdot 6^k$$

$$= 6^{k+1}$$

3. [6 marks] Asymptotic analysis. You may refer to the following definitions for this question.

 $g \in \mathcal{O}(f): \quad \exists c, n_0 \in \mathbb{R}^+, \ \forall n \in \mathbb{N}, \ n \ge n_0 \Rightarrow g(n) \le c \cdot f(n)$ 

 $g \in \Omega(f): \exists c, n_0 \in \mathbb{R}^+, \ \forall n \in \mathbb{N}, \ n \ge n_0 \Rightarrow g(n) \ge c \cdot f(n)$ 

 $g \in \Theta(f): \quad g \in \mathcal{O}(f) \land g \in \Omega(f)$ 

Disprove the following statement. Begin by writing its negation; you may, but are not required to, expand the definitions of Big-Oh, Omega, and/or Theta in the negated statement.

$$\exists a \in \mathbb{R}^+, \ an+1 \in \Theta(n^3)$$

#### Solution

The negation is

$$\forall a \in \mathbb{R}^+, \ an+1 \notin \mathcal{O}(n^3) \lor an+1 \notin \Omega(n^3)$$

*Proof.* Let  $a \in \mathbb{R}^+$ . We'll prove that  $an + 1 \notin \Omega(n^3)$ .

Let  $c, n_0 \in \mathbb{R}^{\geq 0}$ . Let  $n = \left[ \max(n_0, \sqrt{\frac{2a}{c}}, \left(\frac{c}{2}\right)^{\frac{1}{3}} \right] + 1$ . We'll prove that  $n \geq n_0$  and that  $an + 1 < cn^3$ .

**Part 1**: proving that  $n \ge n_0$ .

By the definition of n, we know that  $n \ge \max(n_0, ...) \ge n_0$ .

**Part 2**: proving that  $an + 1 < cn^3$ .

First:

$$n > \sqrt{\frac{2a}{c}}$$
 (by definition of  $n$ ) 
$$n^2 > \frac{2a}{c}$$
 
$$\frac{c}{2}n^3 > an$$
 (multiplying by  $\frac{c}{2}n$ )

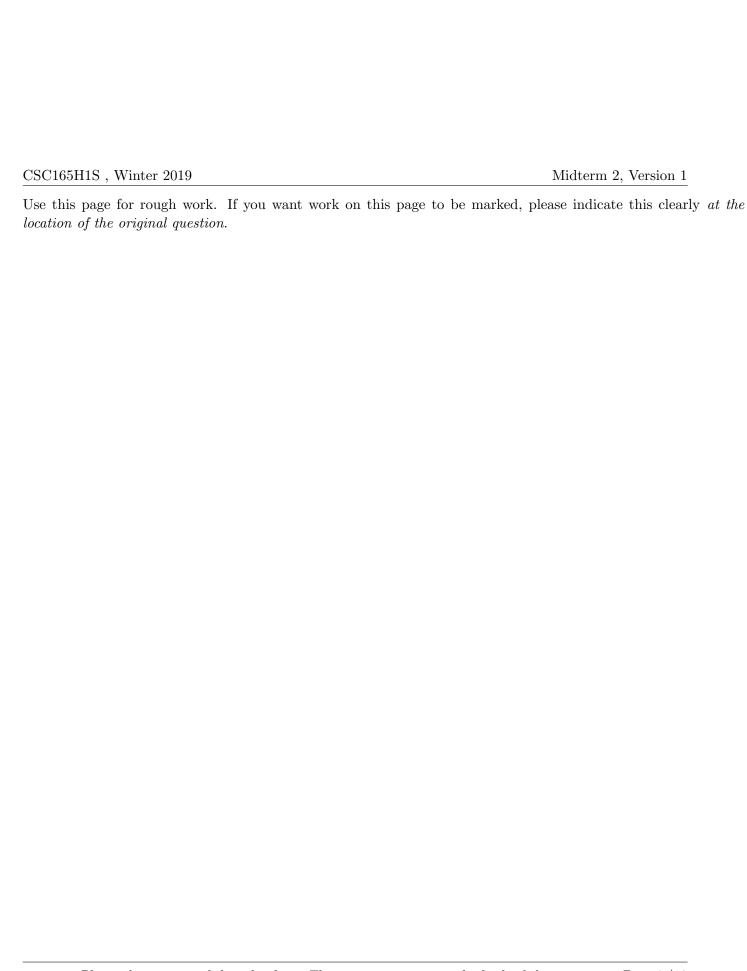

Also:

$$n > \left(\frac{2}{c}\right)^{\frac{1}{3}}$$
 (by definition of  $n$ ) 
$$n^3 > \frac{2}{c}$$
 
$$\frac{c}{2}n^3 > 1$$

CSC165H1S	Winter	2019

Midterm 2, Version 1

Adding these two inequalities yields the desired  $an + 1 < \frac{c}{2}n^3 + \frac{c}{2}n^3 = cn^3$ .

- 4. [9 marks] Running time analysis.
  - (a) [3 marks] Consider the following algorithm.

```
def f(n: int) -> None:
    """Precondition: n >= 0."""
    for i in range(n * n):  # Loop 1
        j = 0
        while j < i:  # Loop 2
        print(j)
        j = j + 3</pre>
```

Find the **exact total number of iterations of Loop 2** when f is run, in terms of its input n. To simplify your calculations, you may ignore floors and ceilings. Use the following formula to simplify any summations you find in your expression (valid for all  $m \in \mathbb{N}$ ):

$$\sum_{i=0}^{m} i = \frac{m(m+1)}{2}$$

Note: make sure to explain your work in English, rather than writing only calculations.

#### Solution

First, we analyse the number of iterations of Loop 2 for a *single* iteration of Loop 1:

• Since j starts at 0 and takes on the values  $0, 3, 6, \ldots$  until its value is  $\geq i$ , Loop 2 takes  $\frac{i}{3}$  iterations (we're ignoring floor/ceiling here).

Next, we need to add up this number over all iterations of Loop 1. Loop 1 runs  $n^2$  iterations, for  $i = 0, 1, ..., n^2 - 1$ . So the total number of iterations of Loop 2 is:

$$\begin{split} \sum_{i=0}^{n^2-1} \frac{i}{3} &= \frac{1}{3} \sum_{i=0}^{n^2-1} i \\ &= \frac{1}{3} \cdot \frac{(n^2-1)n^2}{2} \\ &= \frac{1}{6} n^4 - \frac{1}{6} n^2 \end{split}$$

(b) [6 marks] Consider the following algorithm, which takes as input a list of integers.

Prove matching upper (Big-Oh) and lower (Omega) bounds on the worst-case running time of my\_alg. Clearly label which part of your solution is a proof of the upper bound, and which part is a proof of the lower bound. You may use properties of divisibility (e.g., about even and odd numbers) in your analysis without proving them. You may also use the summation formula from part (a).

HINT: the "obvious" upper bound of  $\mathcal{O}(n^2)$  is too large here.

#### Solution

#### Upper bound on worst-case running time.

Let  $n \in \mathbb{N}$ , and let 1st be an arbitrary list of integers of length n.

The condition of the if statement is satisfied at most once during the execution of the algorithm, because if lst[i] is odd, then the inner loop changes every element in lst[i+1:n] so that it becomes even. Hence, the inner loop runs for at most one value of i.

Since the body of the inner loop takes constant time (1 step) and it iterates for at most  $i \leq n$  iterations, the inner loop takes time  $\mathcal{O}(n)$ .

Since this happens for at most one value of i, the body of the outer loop takes constant time for every other iteration (when the if condition is false) and completes exactly n iterations, for a total time of  $\mathcal{O}(n)$ .

## Lower bound on worst-case running time.

```
Let n \in \mathbb{N} and let 1st = [1, 2, \dots, n].
```

Then the outer loop body takes at least one step and iterates n times, for a total of at least n steps, which is  $\Omega(n)$ .
