# Outline

documentation, special methods for inheritance

abstract data types (ADTs)

implement ADTs with classes, inheritance

balanced parentheses

## avoid duplicating documentation

one place will  
be wrong

don't maintain documentation in **two places** e.g. superclass and subclass, unless there's no other choice:

- ▶ inherited methods, attributes no need to document again
- ▶ extended methods document that they are extended and how — *e.g. call superclass init*
- ▶ overridden methods, attributes document that they are overridden and how

see **Shape** and **Square**

# Pycharm type hinting, redux

be sure to always include the functional annotation (CSC108)  
style of annotation:

```
[...]
```

```
def __init__(self, num: int, name: str) -> None:  
[...]
```

Annotate attributes similarly:

```
x: int
```

see **Shape**

*Pycharm uses  
both to nag you*

## new lists from old

suppose `L` is a list of the first hundred natural numbers:

```
L = list(range(100))
```

if I want a new list with the squares of all the elements of `L` I  
*could*

```
new_list = []
for x in L:
    new_list.append(x * x)
```

you probably have  
to return new-list

or I could use the equivalent list comprehension

```
new_list = [x * x for x in L]
```

expression

iterable (e.g. list)

## filtering with [...]

I can make sure my new list only uses specific elements of the old list...

```
L = ["one", "two", "three", "four", "five", "six"]
```

by adding a condition...

```
new_list = [s * 3  
           for s in L  
           if s <= "one"]
```

*filter, no "else"*

notice that a comprehension can span several lines, if that makes it easier to understand

## general comprehension pattern

[expression for name in iterable if condition]

Python expressions evaluate to values, `name` refers to each element of `iterable` (list, tuple, dictionary, ...) in turn, and a `condition` evaluates to either `True` or `False`

You should be able to read these, even if you don't write them.

see [Code like Pythonista](#)

## common ADTs

In CS we recycle our intuition about the outside world as ADTs. We abstract the data and operations, and suppress the implementation

- ▶ sequences of items; can be added, removed, accessed by position *e.g. Python list...*

- ▶ specialized list where we only have access to most recently added item → *stack*

→ *e.g. Python dictionary...*

- ▶ collection of items accessed by their associated keys

## stack class design

We'll use this real-world description of a stack for our design:

*A **stack** contains items of various sorts. New items are **added** on to the top of the stack, items may only be **removed** from the top of the **stack**. It's a mistake to try to **remove** an item from an **empty** **stack**, so we need to know if it **is empty**. We can tell how big a stack is.*

Take a few minutes to identify the main noun, verb, and attributes of the main noun, to guide our class design. Remember to be flexible about alternate names and designs for the same class

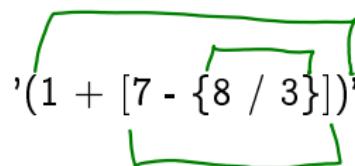

# implementation possibilities

The public interface of our Stack ADT should be constant, but inside we could implement it in various ways

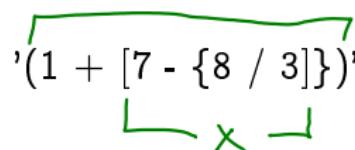

- ▶ Use a python list, which already has a pop method and an append method  
- both from high end of list ...
- ▶ Use a python list, but add and remove from position 0  
- some extra work
- ▶ Use a python dictionary with integer keys 0, 1, ..., keeping track of the last index used, and which have been removed  
- a little extra work, but fast ...

## parenthesization

In some situations it is important that opening and closing parentheses, brackets, braces match.

 
$$'(1 + [7 - \{8 / 3\}])'$$
 good

The expression is shown with three levels of brackets: parentheses {}, brackets [], and braces {}. Each level has a green bracket above it, indicating they are properly matched.

 
$$'(1 + [7 - \{8 / 3\}])'$$
 bad

The expression is shown with three levels of brackets: parentheses {}, brackets [], and braces {}. The braces {} are not properly matched with the brackets [], as indicated by a green bracket above the braces and a green 'X' and a green dash below the brackets, suggesting a mismatch.

Remember, the computer only “sees” one character at a time.

define balanced parentheses:

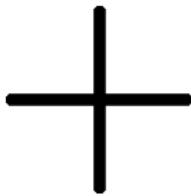

(a recursive definition)

- ▶ a string with no parentheses is balanced
- ▶ a string that begins with a left parenthesis "(", ends with a right parenthesis ")", and in between has balanced parentheses is balanced. Same for brackets "[...]" and braces "..."
- ▶ the concatenation of two strings with balanced parentheses is also balanced

Stack  $\rightarrow$  (

(

# 1

Stack  $\rightarrow$  [ (

[

.

# 7

stack  $\rightarrow \{$

$\lfloor$   
 $\lfloor$

$\}$

# 8

# 3

Stack → [  
[

} ✓ ok!

Stack>(

]

OK

]  
X (

↓  
mismatch!

## sack ADT

Here's a description of a sack, which has similar features to a stack:

*A **sack** contains items of various sorts. New items are **added** on to a random place in the **sack**, so the order items are **removed** from the **sack** is completely unpredictable. It's a mistake to try to **remove** an item from an **empty sack**, so we need to know if it **is empty**. We can tell how big a sack is.*

Take a few minutes to identify the main noun, verb, and attributes of the main noun, to guide our class design. Remember to be flexible about alternate names and designs for the same class

## generalize stack, sack as Container

stacks and sacks can have different implementations: using python lists, dictionaries, ... so it doesn't make sense to have the implementation in a superclass. However, it is nice to have a common API between the two, so we can write client code that works with any stack, sack, or other... Containers

```
# suppose L is list[Container]
```

```
for c in L:  
    for i in range(1000):  
        c.add(i)  
    while not c.is_empty():  
        print(c.remove())
```

pycharm + other  
tools know c has a  
add method, so they  
chill...

... so we'll make Stack, Sack subclasses of Container!

# hand-rolled Exception

- ▶ what happens when you remove something from an empty Container?  
*Error, but message depends on implementation (list, dict ...)*
- ▶ the contract is honoured, but can we do better?  
*Give the client more clues: ...*
- ▶ easy class implementation: EmptyContainerException

*declare this!*

## testing

Use your docstring for testing as you develop, but use **unit testing** to make sure that your particular implementation remains consistent with your ADT's interface. Be sure to:

- ▶ import the module `unittest`
- ▶ subclass `unittest.TestCase` for your tests, and begin each method that carries out a test with the string `test`  
`def test....( ) :`
- ▶ compose **tests** before and **during** implementation

## chosing test cases

since you can't test every input, try to think of **representative** cases:

- ▶ smallest argument(s): 0, empty list or string, ...
- ▶ boundary case: moving from 0 to 1, empty to non-empty, ...
- ▶ “typical” case

if your function had a str and an int argument, that would mean  $3 \times 3$  tests (minimum)!

# isolate units

- ▶ test classes separately
- ▶ test (related) methods separately

why?

Pinpoint  
problem  
Code!
